Outline

- ① Problem Description
- ② Graph Attention Networks (GATs)
- ③ Network Architecture
- ④ Experimental Setup
- ⑤ Training Phase
- ⑥ Testing Phase
- ⑦ Results

Problem Description

Zero-shot video object segmentation (ZVOS) refers to the problem of segmenting one or more objects in a video without having access to any pixel-level annotations (masks) of those objects at test time, and without requiring that the model has seen the exact object category during training.

Problem Description

Formally, let

$$I = \{ I_i \in \mathbb{R}^{H \times W \times 3} \mid i = 1, \dots, N \}$$

be a sequence of N color frames (height H , width W). The goal is to predict a **Segmentation Mask**

$$S = \{ S_i \in \{0, 1\}^{H \times W} \mid i = 1, \dots, N \}$$

where

$$S_i(x, y) = \begin{cases} 1 & \text{if pixel } (x, y) \text{ belongs to a primary object (foreground)} \\ 0 & \text{if pixel } (x, y) \text{ is background} \end{cases}$$

Why ZVOS is a challenging task

- **No mask supervision at test time:** the model must infer foreground without any ground-truth annotations
- **Unseen categories:** objects in the video may belong to classes never encountered during training
- **Large appearance variation:** changes in scale, pose, lighting, and background over time
- **Occlusions and fast motion:** partial/full occlusion and motion blur make tracking and segmentation harder
- **Background clutter:** dynamic or textured backgrounds can confuse foreground detection
- **Temporal consistency:** maintaining coherent masks across frames without drift or fragmentation

Graph Attention Networks (GATs)

• GATs

- Weights neighbor-node contributions instead of uniform aggregation
- **Assign higher importance to more relevant neighbors** during message passing
- **Dynamically adjust neighbor's influence** for more expressive node representations

• AGNN Extension

- **Adapts attention to pixel-wise relations** within and between video frames
- **Captures higher-order dependencies** ideal for zero-shot video object segmentation

AGNN for Zero-Shot Video Object Segmentation

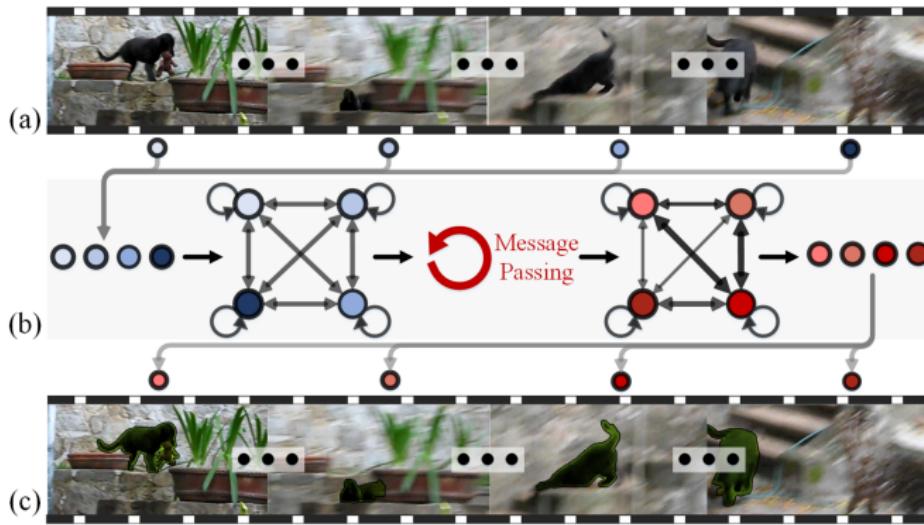

Figure: AGNN for ZVOS

Network Architecture

- ① FCN-Based Node Embedding
- ② Intra-Attention Based Loop-Edge Embedding
- ③ Inter-Attention Based Line-Edge Embedding
- ④ Gated Message Aggregation
- ⑤ ConvGRU Based Node-State Update
- ⑥ Read-Out Function

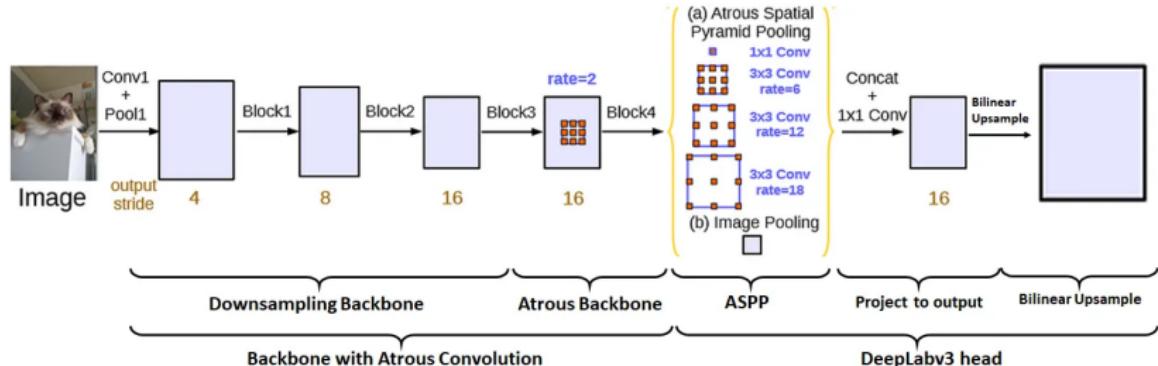

FCN-Based Node Embedding - DeepLabV3

- Use **DeepLabV3** (a Fully Convolutional Network for semantic segmentation) to extract initial node embeddings:

$$h_i^0 = v_i = F_{\text{DeepLab}}(I_i) \in \mathbb{R}^{H \times W \times C}$$

- **Embeddings preserve spatial structure and high-level semantic features**, essential for pixel-wise segmentation
- **Atrous (dilated) convolutions enlarge the receptive field** without losing resolution
- **Atrous Spatial Pyramid Pooling** (ASPP) applies parallel dilated convolutions at multiple rates to **capture multi-scale context**
- Output: spatially aware and semantically rich feature maps

DeepLabV3

(a)

Intra-Attention Based Loop-Edge Embedding

- A **loop-edge** $e_{i,i}$ **connects node v_i to itself** in the AGNN graph
- Its **embedding** $e_{i,i}^k$ is computed by:

$$e_{i,i}^k = \alpha \cdot \text{SoftMax}\left(\left(W_f * h_i^k\right)\left(W_h * h_i^k\right)^T\right)\left(W_\ell * h_i^k\right) + h_i^k$$

- **Intra-attention models long-range dependencies within the same frame**
- **Preserves spatial structure**
- α is a learnable scalar; W_f, W_h, W_ℓ are convolution kernels

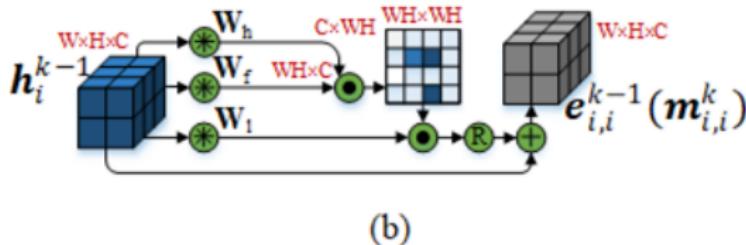

Inter-Attention Line-Edge Embedding

- A **line-edge** $e_{i,j}$ **connects node** v_i **to node** v_j
- Inter-attention computes:

$$\begin{cases} e_{i,j}^k = h_i^k W_c (h_j^k)^T \\ e_{j,i}^k = (e_{i,j}^k)^T \end{cases}$$

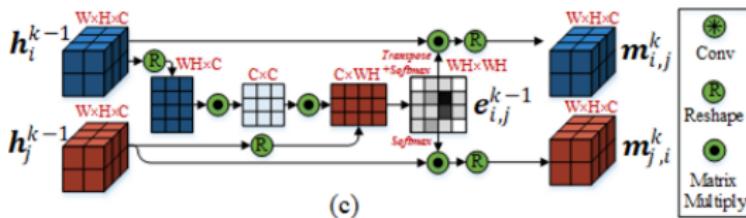

- $W_c \in \mathbb{R}^{C \times C}$ learnable weight matrix; $h_i^k \in \mathbb{R}^{(W H) \times C}$ flattened feature tensors
- **The embedding $e_{i,j}^k$ measures how strongly v_i influences v_j during message passing**
- Allows discovering semantic matches between frames without recurring to explicit optical flow

Attention Mechanisms

(b)

Figure: intra-attention

(c)

Figure: inter-attention

Gated Message Aggregation

- **Self-Loop Message**

$$m_{i,i}^k = e_{i,i}^{k-1}$$

- **Neighbor Message**

$$m_{j,i}^k = M(h_j^{k-1}, e_{j,i}^{k-1}) = \text{SoftMax}(e_{j,i}^{k-1}) h_j^{k-1}$$

- $\text{SoftMax}(e_{j,i}^{k-1})$ normalizes each row of the edge embedding, turning it into weights over spatial positions
- After computing, reshape $m_{j,i}^k$ back into a $W \times H \times C$ tensor
- Aggregating messages lets **each node gather information from itself and neighbors**
- Attention ensures **nodes focus only on the most useful parts of a neighbor's features**

Gated Message Aggregation

- **Learnable Gating** After forming each message $m_{j,i}^k \in \mathbb{R}^{W \times H \times C}$, we compute a **confidence score per channel**:

$$g_{j,i}^k = G(m_{j,i}^k) = \sigma(\text{GAP}(W_g * m_{j,i}^k + b_g)) \in [0, 1]^C$$

- GAP(\cdot) applies global-average pooling over spatial dimensions, **summarizing each channel into one scalar**
- A sigmoid $\sigma(\cdot)$ then maps these summaries into $[0, 1]$, producing **one gating coefficient per channel**
- Channels with higher $g_{j,i}^k(c)$ are considered more reliable and will pass through

Gated Message Aggregation

- **Gated Aggregation** Combine all self-loop and neighbor messages, but modulate each by its gate:

$$m_i^k = \sum_{v_j \in \mathcal{V}} g_{j,i}^k \odot m_{j,i}^k$$

where \odot denotes channel-wise (Hadamard) multiplication:
 $(g \odot m)(x, y, c) = g(c) m(x, y, c)$

- **Why include gating?**
 - Not all neighbors are equally informative - some may be noisy (occluded, out-of-focus,...)
 - The gate learns to down-weight unreliable channels, **improving robustness**
 - Aggregating only the “trusted” features leads to **cleaner node updates** and better performance on noisy video frames

ConvGRU-Based Node-State Update

- At iteration k , given previous state h_i^{k-1} and aggregated message m_i^k :

$$h_i^k = U_{\text{ConvGRU}}(h_i^{k-1}, m_i^k) \in \mathbb{R}^{W \times H \times C}$$

- GRU gates decide how much past vs. new information to use**
- Convolutional layers replace dense multiplications, **preserving spatial structure**
- Gates:**
 - Update gate:** Controls incorporation of new message
 - Reset gate:** Controls forgetting of previous state when computing candidate

ConvGRU Benefits

- **Spatial consistency:** since all operations are convolutional, the new state retains spatial structure (H, W)
- **Parameter efficiency:** fewer learnable parameters than fully connected GRU
- **Temporal memory:** over multiple message-passing iterations the hidden state carries forward spatial features refined by earlier rounds of attention and gating
- **Channel-wise adaptivity:** the update and reset gates operate per-channel and per-pixel, allowing more flexibility

Read-Out Function

- After K message-passing iterations, concatenates the final state h_i^K and initial state h_i^0 along the channel axis to find the **predicted segmentation mask**:

$$\hat{S}_i = \text{R}_{\text{FCN}}([h_i^K, h_i^0]) \in [0, 1]^{W \times H}$$

- Architecture:**
 - Two 3×3 convolutional layers to refine features
 - One 1×1 convolutional layer followed by sigmoid to produce a normalized pixel-wise mask
- Key Point:** Implemented as a **lightweight FCN** to preserve **spatial resolution** and **global and local context awareness**

AGNN Network

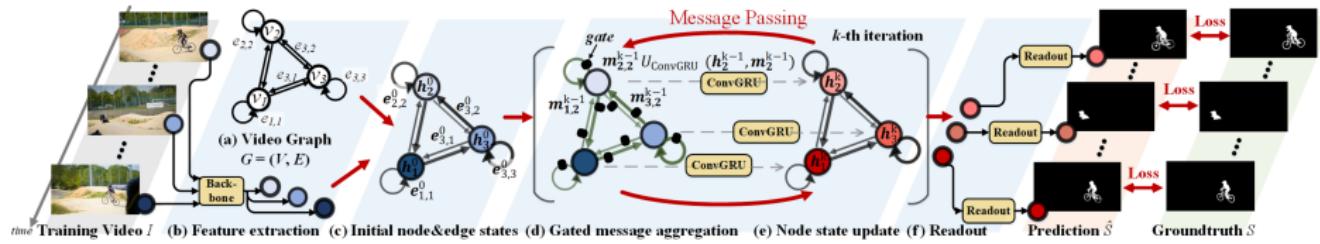

Figure: AGNN during training

Loss Function

- Pixel-level weighted binary cross-entropy

$$L(S, \hat{S}) = - \sum_{x=1}^{W \times H} \left[(1 - \eta) S_x \log(\hat{S}_x) + \eta (1 - S_x) \log(1 - \hat{S}_x) \right].$$

- Where:

- $S_x \in \{0, 1\}$: ground-truth label at pixel x
- $\hat{S}_x \in [0, 1]$: predicted probability at pixel x
- η : ratio of foreground to background pixels in S

- Mitigate class imbalance

- Encourages the model to **learn features that correctly segment objects** rather than defaulting to background
- Weighted loss helps **AGNN learn robust object-level features**

Environment Details

- **OS:** Ubuntu 22.04 LTS on WSL2
- **CPU:** 12th Gen Intel Core i7-12700KF (10 cores / 20 threads)
- **GPU:** NVIDIA RTX 3060 (12 GB GDDR6, Driver 572.61, cuDNN 8.3)
- **Python / Libraries:** Python 3.10, PyTorch 1.13.1, CUDA 11.6

Dataset and Metrics

- **Dataset:** DAVIS17 - A benchmark for video object segmentation, featuring high-resolution video sequences with pixel-level annotations for multiple objects across frames
- **Region Similarity J (IoU):** Average Intersection-over-Union between each predicted mask and ground truth, computed over all frames
- **Boundary Accuracy F :** Contour measure between predicted and ground truth boundaries, using a 2-pixel tolerance
- **Temporal Stability T :** Measures how smoothly the predicted mask evolves between consecutive frames. In other words, it is high when most of the object area stays consistent from frame t to frame $t + 1$

Training Setup

- **Sampling Strategy:**

- Split each training video (length N frames) into N' segments
- Randomly select one frame from each segment for training

- **Implementation Details:**

- Due to computational limits, select 2 training videos per batch
- Set $N' = 3$ (one frame from each of 3 segments)
- Number of message-passing iterations $K = 3$
- Trained for 100 epochs total

Training

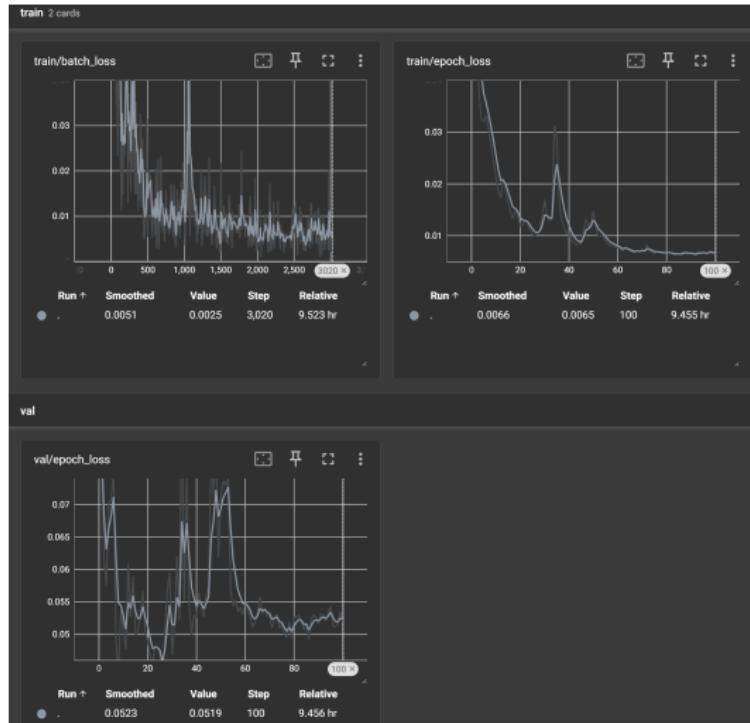

Figure: Training and validation loss

Training

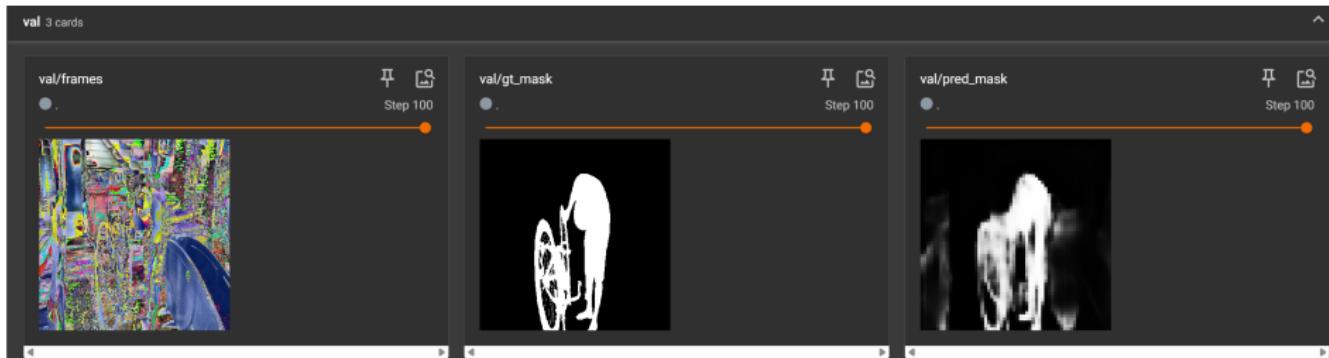

Figure: Validation

Testing Setup

- Select an input video I of N frames at 473×473 resolution
- Split I into $T = \frac{N}{N'}$ subsets: $\{I_1, \dots, I_T\}$
- Each subset I_t contains N' frames:
$$\{I_t, I_{t+T}, \dots, I_{N-T+t}\}$$
- Feed each subset into AGNN to obtain segmentation masks for its frames
- **Apply Conditional Random Field (CRF) as post-processing to refine boundaries**

Examples

Figure: Frame from Balckswan video: $\bar{J} = 0.886$; $\bar{F} = 0.701$; $\bar{T} = 0.906$

Figure: Frame from Breakdance $\bar{J} = 0.317$; $\bar{F} = 0.190$; $\bar{T} = 0.120$

Results Summary - DAVIS17

	\bar{J}	\bar{F}	\bar{T}
Overall Mean	0.635	0.406	0.723

Video	\bar{J}	\bar{F}	\bar{T}
blackswan	0.886	0.701	0.906
lab-coat	0.919	0.637	0.884
cows	0.827	0.507	0.945
car-shadow	0.770	0.455	0.875
breakdance	0.317	0.190	0.120
india	0.179	0.200	0.338

Interpreting the Results - DAVIS17

- **High-Scoring Videos** (e.g., blackswan, lab-coat, cows):
 - Large, high-contrast foreground occupies most of the frame
 - Minimal occlusion and smooth, predictable motion
- **Low-Scoring Videos** (e.g., breakdance, india):
 - Rapid, erratic motion and cluttered backgrounds (breakdance) or very small, low-contrast objects (india)
 - Fixed receptive field struggles to extract stable foreground signals under these conditions
- **Boundary vs. Region Scores:**
 - High IoU (region) but mask contours often lie several pixels away from ground-truth edges, lowering the boundary F-measure

Conclusions

- **Attentive Graph Neural Network:** constructs a fully-connected graph over video frames as nodes, with learnable attention edges
- **Dual attention mechanisms:** intra-attention for self-context and inter-attention for pairwise frame dependencies, all while preserving spatial maps
- **Adaptive message fusion:** gated aggregation plus ConvGRU updates enable the model to selectively retain old information and incorporate new information
- **Spatially-aware segmentation:** convolutional readout layers tailor the per-pixel zero-shot segmentation task, keeping fine boundary detail
- **State-of-the-art performance:** AGNN achieves new benchmarks on DAVIS17 ($\overline{J\&F} = 61.1$ vs. 43.7) and YouTube-Objects (mean $F = 70.8$)
